Analyze A/B Test Results

This project will assure you have mastered the subjects covered in the statistics lessons. The hope is to have this project be as comprehensive of these topics as possible. Good luck!

Table of Contents

- Introduction
- Part I Probability
- Part II A/B Test
- Part III Regression

Introduction

A/B tests are very commonly performed by data analysts and data scientists. It is important that you get some practice working with the difficulties of these

For this project, you will be working to understand the results of an A/B test run by an e-commerce website. Your goal is to work through this notebook to help the company understand if they should implement the new page, keep the old page, or perhaps run the experiment longer to make their decision.

As you work through this notebook, follow along in the classroom and answer the corresponding quiz questions associated with each question. The labels for each classroom concept are provided for each question. This will assure you are on the right track as you work through the project, and you can feel more confident in your final submission meeting the criteria. As a final check, assure you meet all the criteria on the RUBRIC.

Part I - Probability

To get started, let's import our libraries.

In [1]: import pandas as pd
 import numpy as np
 import random
 import matplotlib.pyplot as plt

```
%matplotlib inline
#We are setting the seed to assure you get the same answers on quizzes as we set up
random.seed(42)
```

- 1. Now, read in the ab_data.csv data. Store it in df . Use your dataframe to answer the questions in Quiz 1 of the classroom.
- a. Read in the dataset and take a look at the top few rows here:

```
In [2]: #read 'ab_data.csv' file and sort in df
    df = pd.read_csv('ab_data.csv')
    df.head()
```

Out[2]:	user_id		timestamp	group	landing_page	converted
	0	851104	2017-01-21 22:11:48.556739	control	old_page	0
	1	804228	2017-01-12 08:01:45.159739	control	old_page	0
	2	661590	2017-01-11 16:55:06.154213	treatment	new_page	0
	3	853541	2017-01-08 18:28:03.143765	treatment	new_page	0
	4	864975	2017-01-21 01:52:26.210827	control	old_page	1

b. Use the below cell to find the number of rows in the dataset.

```
In [3]: print('Rows: {}'.format(df.shape[0]))
```

Rows: 294478

c. The number of unique users in the dataset.

```
In [4]: print('Unique Users: {}'.format(df.user_id.nunique()))
```

Unique Users: 290584

d. The proportion of users converted.

```
In [5]: print('Convert Rate: {}'.format(df.converted.mean()))
```

Convert Rate: 0.11965919355605512

e. The number of times the new_page and treatment don't line up.

```
In [6]: print('Inaccurate Rows: {}'.format(df[(df['landing_page'] == 'new_page') != (df['group'] == 'treatment')].shape[0]))
Inaccurate Rows: 3893
f. Do any of the rows have missing values?
```

- 2. For the rows where **treatment** is not aligned with **new_page** or **control** is not aligned with **old_page**, we cannot be sure if this row truly received the new or old page. Use **Quiz 2** in the classroom to provide how we should handle these rows.
- a. Now use the answer to the quiz to create a new dataset that meets the specifications from the quiz. Store your new dataframe in **df2**.

```
In [8]: # Remove the inaccurate rows, and store the result in a new dataframe df2
df2 = df[(df['landing_page'] == 'new_page') == (df['group'] == 'treatment')]
df2.head()
```

```
Out[8]:
            user id
                                                  group landing_page converted
                                   timestamp
         0 851104 2017-01-21 22:11:48.556739
                                                             old_page
                                                                               0
                                                 control
         1 804228 2017-01-12 08:01:45.159739
                                                 control
                                                             old_page
                                                                               0
         2 661590 2017-01-11 16:55:06.154213 treatment
                                                                               0
                                                             new_page
         3 853541 2017-01-08 18:28:03.143765 treatment
                                                                               0
                                                             new_page
         4 864975 2017-01-21 01:52:26.210827
                                                 control
                                                             old_page
                                                                               1
```

```
Out[10]:
          3. Use df2 and the cells below to answer questions for Quiz3 in the classroom.
          a. How many unique user_ids are in df2?
         print('Unique Users: {}'.format(df2.user id.nunique()))
In [11]:
          Unique Users: 290584
          b. There is one user_id repeated in df2. What is it?
         #Display the repeated user id
In [12]:
          df2[df2.user id.duplicated()]['user id']
                  773192
Out[12]:
          Name: user id, dtype: int64
          c. What is the row information for the repeat user_id?
         #Display row information for the repeated user id
In [13]:
          df2[df2.user id.duplicated(keep=False)]
Out[13]:
                user_id
                                     timestamp
                                                  group landing_page converted
          1899 773192 2017-01-09 05:37:58.781806 treatment
                                                                              0
                                                             new_page
          2893 773192 2017-01-14 02:55:59.590927 treatment
                                                                              0
                                                             new_page
          d. Remove one of the rows with a duplicate user_id, but keep your dataframe as df2.
         #Remove one of the rows with a duplicate user_id
          df2 = df2.drop duplicates('user id')
         print('Unique Rows: {}'.format(df2.shape[0]))
In [15]:
          Unique Rows: 290584
```

- 4. Use **df2** in the below cells to answer the guiz guestions related to **Quiz 4** in the classroom.
- a. What is the probability of an individual converting regardless of the page they receive?

```
#Calculate the population converted rate
In [16]:
          p population = df2['converted'].mean()
          p_population
         0.11959708724499628
Out[16]:
         b. Given that an individual was in the control group, what is the probability they converted?
         #Calculate the control group converted rate
In [17]:
          p control = df2.query("group == 'control'")['converted'].mean()
          p control
         0.1203863045004612
Out[17]:
         c. Given that an individual was in the treatment group, what is the probability they converted?
         #Calculate the treatment group converted rate
In [18]:
          p treatment = df2.query("group == 'treatment'")['converted'].mean()
          p treatment
         0.11880806551510564
Out[18]:
In [19]: #Calculate the actual difference (obs diff) between the conversion rates for the two groups
          obs_diff = p_treatment - p_control
          obs diff
          -0.0015782389853555567
Out[19]:
         d. What is the probability that an individual received the new page?
         #Calculate the probability that an individual received the new page
In [20]:
         df2.query("landing page == 'new page'").shape[0] / df2.shape[0]
         0.5000619442226688
Out[20]:
```

e. Consider your results from a. through d. above, and explain below whether you think there is sufficient evidence to say that the new treatment page leads to more conversions.

*Probability of converting regardless of page is 0.1196.

Given that an individual was in the control group, the probability of converting is 0.1204.

Given that an individual was in the treatment group, the probability of converting is 0.1188.

The probability of receiving the new page is 0.50.

So it is very hard to tell which page leads to more conversions than another, and we need to implement an experiment to see if the difference is statistically significant.*

Part II - A/B Test

Notice that because of the time stamp associated with each event, you could technically run a hypothesis test continuously as each observation was observed.

However, then the hard question is do you stop as soon as one page is considered significantly better than another or does it need to happen consistently for a certain amount of time? How long do you run to render a decision that neither page is better than another?

These questions are the difficult parts associated with A/B tests in general.

1. For now, consider you need to make the decision just based on all the data provided. If you want to assume that the old page is better unless the new page proves to be definitely better at a Type I error rate of 5%, what should your null and alternative hypotheses be? You can state your hypothesis in terms of words or in terms of p_{old} and p_{new} , which are the converted rates for the old and new pages.

$$H_o: p_{new} - p_{old} <= 0$$

$$H_1: p_{new}-p_{old}>0$$

2. Assume under the null hypothesis, p_{new} and p_{old} both have "true" success rates equal to the **converted** success rate regardless of page - that is p_{new} and p_{old} are equal. Furthermore, assume they are equal to the **converted** rate in **ab_data.csv** regardless of the

page.

Use a sample size for each page equal to the ones in **ab_data.csv**.

Perform the sampling distribution for the difference in **converted** between the two pages over 10,000 iterations of calculating an estimate from the null.

Use the cells below to provide the necessary parts of this simulation. If this doesn't make complete sense right now, don't worry - you are going to work through the problems below to complete this problem. You can use **Quiz 5** in the classroom to make sure you are on the right track.

a. What is the **convert rate** for p_{new} under the null?

```
In [21]: #Assume under the null hypothesis that the new page converted rate equal to population converted rate
p_new = df2.converted.mean()
p_new
```

Out[21]: 0.11959708724499628

b. What is the **convert rate** for p_{old} under the null?

```
In [22]: #Assume under the null hypothesis that the old page converted rate equal to population converted rate p_old = df2.converted.mean() p_old
```

Out[22]: 0.11959708724499628

c. What is n_{new} ?

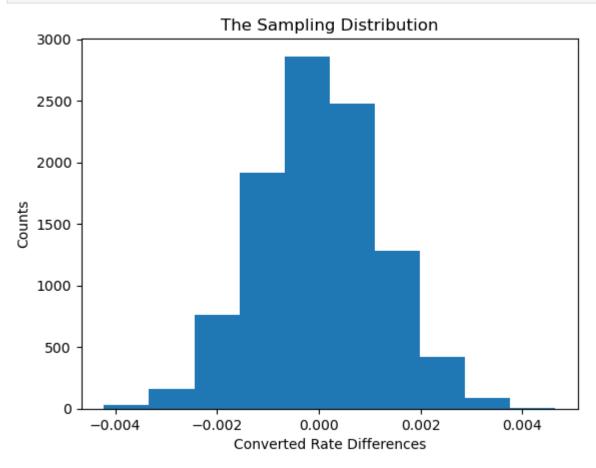

```
In [23]: #Calculate the number of individuals that received the new page
n_new = df2.query('landing_page == "new_page"').shape[0]
n_new
```

```
145310
Out[23]:
          d. What is n_{old}?
          #Calculate the number of individuals that received the old page
In [24]:
          n old = df2.query('landing page == "old page"').shape[0]
          n old
          145274
Out[24]:
          e. Simulate n_{new} transactions with a convert rate of p_{new} under the null. Store these n_{new} 1's and 0's in new_page_converted.
          #Simulate Sample for the treatment Group
In [25]:
          new page converted = np.random.choice(2, n new, [1-p new, p new])
          f. Simulate n_{old} transactions with a convert rate of p_{old} under the null. Store these n_{old} 1's and 0's in old page converted.
          #Simulate Sample for the control Group
In [26]:
          old page converted = np.random.choice(2, n old, [1-p old, p old])
          g. Find p_{new} - p_{old} for your simulated values from part (e) and (f).
In [27]: #Find the difference in the converted probability for the simulated samples
          new page converted.mean() - old page converted.mean()
          0.0021057301266188544
Out[27]:
          h. Simulate 10,000 p_{new} - p_{old} values using this same process similarly to the one you calculated in parts a. through g. above. Store all
          10,000 values in a numpy array called p_diffs.
         #Simulate the sampling distributions 10,000 times
In [28]:
          new converted simulation = np.random.binomial(n new, p new, 10000)/n new
          old converted simulation = np.random.binomial(n_old, p_old, 10000)/n_old
          p diffs = new converted simulation - old converted simulation
```

i. Plot a histogram of the **p_diffs**. Does this plot look like what you expected? Use the matching problem in the classroom to assure you fully understand what was computed here.

```
In [29]: #Plot the sampling distribution of the difference under the null

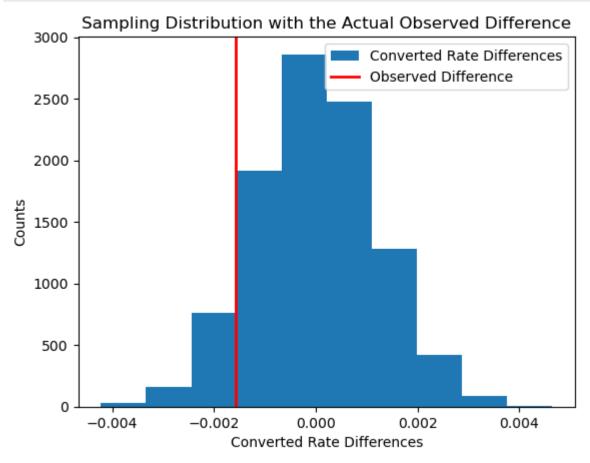

plt.hist(p_diffs)
plt.xlabel('Converted Rate Differences')
plt.ylabel('Counts')
plt.title('The Sampling Distribution')
plt.show()
```

j. What proportion of the **p_diffs** are greater than the actual difference observed in **ab_data.csv**?

```
In [30]: #Plot the Sampling Distribution with the Actual Observed Difference
plt.hist(p_diffs, label='Converted Rate Differences')
plt.axvline(obs_diff, color='r', linewidth=2, label='Observed Difference')
plt.xlabel('Converted Rate Differences')
plt.ylabel('Counts')
```

```
plt.title('Sampling Distribution with the Actual Observed Difference')
plt.legend()
plt.show()
```

```
In [31]: #Calculate P_value
    (p_diffs > obs_diff).mean()
Out[31]: 0.9074
```

k. In words, explain what you just computed in part **j.** What is this value called in scientific studies? What does this value mean in terms of whether or not there is a difference between the new and old pages?

The p_value (0.9) is greater than a (0.05) so we fail to reject the null hypothesis, we can't assume that the new page is better than the old page.

I. We could also use a built-in to achieve similar results. Though using the built-in might be easier to code, the above portions are a walkthrough of the ideas that are critical to correctly thinking about statistical significance. Fill in the below to calculate the number of conversions for each page, as well as the number of individuals who received each page. Let n_old and n_new refer the the number of rows associated with the old page and new pages, respectively.

```
In [32]: import statsmodels.api as sm
         # number of conversions with the old page
          convert old = df2.query("landing page == 'old page'")['converted'].sum()
          # number of conversions with the new page
          convert new = df2.query("landing page == 'new page'")['converted'].sum()
          # number of individuals who were shown the old page
         n old = df2.query("landing page == 'old page'").shape[0]
          # number of individuals who received new page
         n new = df2.query("landing page == 'new page'").shape[0]
In [33]: print('convert old = {} , convert new = {} , n old = {}, n new = {}'.format(convert old, convert new, n old, n new))
         convert old = 17489 , convert new = 17264 , n old = 145274, n new = 145310
         m. Now use stats.proportions ztest to compute your test statistic and p-value. Here is a helpful link on using the built in.
         #Calculate zstat and p value for z test
In [34]:
          count array = np.array([convert new, convert old])
         nobs array = np.array([n new, n old])
          zstat, p value = sm.stats.proportions ztest(count array, nobs array, alternative='larger')
          zstat, p_value
         (-1.3109241984234394, 0.9050583127590245)
Out[34]:
```

n. What do the z-score and p-value you computed in the previous question mean for the conversion rates of the old and new pages? Do they agree with the findings in parts **j.** and **k.**?

* $Z_{-1.31}$: 0.095 is less than $Z_{0.05}$: 1.645, and p_value: 0.91 is greater than a: 0.05 So we fail to reject the null hypothesis, we can't assume that the new page is better than the old page*

Part III - A regression approach

- 1. In this final part, you will see that the result you acheived in the previous A/B test can also be acheived by performing regression.
- a. Since each row is either a conversion or no conversion, what type of regression should you be performing in this case?

Logistic Regression Model.

b. The goal is to use **statsmodels** to fit the regression model you specified in part **a.** to see if there is a significant difference in conversion based on which page a customer receives. However, you first need to create a column for the intercept, and create a dummy variable column for which page each user received. Add an **intercept** column, as well as an **ab_page** column, which is 1 when an individual receives the **treatment** and 0 if **control**.

```
In [35]: #Add intercept column
df2['intercept'] = 1

#Add ab_page a dummy variable column, having a value 1 when an individual receives the treatment, otherwise 0.
df2['ab_page'] = pd.get_dummies(df2['group'])['treatment']
df2.head()
```

Out[35]:		user_id	timestamp	group	landing_page	converted	intercept	ab_page
	0	851104	2017-01-21 22:11:48.556739	control	old_page	0	1	0
	1	804228	2017-01-12 08:01:45.159739	control	old_page	0	1	0
	2	661590	2017-01-11 16:55:06.154213	treatment	new_page	0	1	1
	3	853541	2017-01-08 18:28:03.143765	treatment	new_page	0	1	1
	4	864975	2017-01-21 01:52:26.210827	control	old_page	1	1	0

c. Use **statsmodels** to import your regression model. Instantiate the model, and fit the model using the two columns you created in part **b.** to predict whether or not an individual converts.

```
In [36]: #Instantiate and fit the logistic regression model
lm = sm.Logit(df2['converted'], df2[['intercept', 'ab_page']])
res = lm.fit()
print(res.summary2())
```

Optimization terminated successfully.

Current function value: 0.366118

Iterations 6

Results: Logit

	=========					======	====	====	======	

e. What is the p-value associated with **ab_page**? Why does it differ from the value you found in **Part II**?

*At part II we perform one-tailed test: $H_o: p_{new}-p_{old} <= 0, H_1: p_{new}-p_{old} > 0$ At the logistic regression model we perform two-tailed test: $H_0: \beta_1 = 0, H_1: \beta_1 \neq 0$ The p_value (0.19) is greater than a (0.05) which means there's no relationship between converted rate and the landing page.

f. Now, you are considering other things that might influence whether or not an individual converts. Discuss why it is a good idea to consider other factors to add into your regression model. Are there any disadvantages to adding additional terms into your regression model?

*It's a good idea to add other factors into the regression model becouse it increase the ability to determine the relative influence of one or more predictor variables to the criterion value, and increase the ability to identify outliers, or anomalies.

A disadvantage of multiple factors in a regression model is reduces the power of analysis, and Adding an irrelevant variable can increase the variance of the estimate of other correlation coefficient and will not have any benefits.*

g. Now along with testing if the conversion rate changes for different pages, also add an effect based on which country a user lives. You will need to read in the **countries.csv** dataset and merge together your datasets on the appropriate rows. Here are the docs for joining tables.

Does it appear that country had an impact on conversion? Don't forget to create dummy variables for these country columns - **Hint:**You will need two columns for the three dummy variables. Provide the statistical output as well as a written response to answer this question.

```
#Read countries.csv file into countries df
In [37]:
          countries df = pd.read csv('countries.csv')
          #Join df2 with countries df into a new dataframe df merged
          df merged = df2.set index('user id').join(countries df.set index('user id'), on='user id', how='inner')
          df merged.head()
Out[37]:
                                timestamp
                                              group landing_page converted intercept ab_page country

```

*All p_values are greater than a (0.05) which means there's no relationship between the country or page with the converted rate.

h. Though you have now looked at the individual factors of country and page on conversion, we would now like to look at an interaction between page and country to see if there significant effects on conversion. Create the necessary additional columns, and fit the new model.

Provide the summary results, and your conclusions based on the results.

```
In [40]: df_merged['CA_page'] = df_merged['CA'] * df_merged['ab_page']
    df_merged['UK_page'] = df_merged['UK'] * df_merged['ab_page']
    df_merged.head()
```

```

*All p_values are greater than a (0.05) ,So we fail to reject the null hypothesis which means that the interaction between country and page has no effects on the converted rate.

Conclusions

After performing the three methods of A/B testing (Sampling Distributions, Z-test and Logistic Regression), we fail to reject the null hypothesis that means the new and old page have an approximately equal chance of converting users. I recommend to the e-commerce company to keep the old page. This will save time and money on creating a new page.
